

2016 NCTS International Workshop on Mathematical Biology

May 21-23, 2016

Venue: National Tsing Hua University, Hsinchu, Taiwan

May 21, 2016

8:30am-9:00am Registration

9:00am-9:45am Spatial heterogeneity and time periodicity in Lotka-Volterra competition-diffusion systems

Prof. **Wei-Ming Ni**, East China Normal University and University of Minnesota

Chair: Prof. Sze-Bi Hsu

10:00am-10:45am Traveling waves for a lattice dynamical system arising in a diffusive endemic model

Prof. **Jong-Sheng Guo**, Tamkang University

Chair: Prof. Je-Chiang Tsai

11:00am-11:30am Bistable traveling waves for monotone semiflows

Prof. **Jian Fang**, Harbin Institute of Technology

Chair: Prof. Yijun Lou

11:35am-12:05pm An approach to the asymptotic behavior of traveling waves for some lattice dynamical systems

Prof. **Chang-Hong Wu**, National University of Tainan

Chair: Prof. Yijun Lou

12:05pm-2:00pm Lunch break

2:00pm-2:45pm Fronts and pulses in FitzHugh-Nagumo equations

Prof. **Chao-Nien Chen**, National Tsing Hua University

Chair: Prof. Ying-Hen Hsieh

3:00pm-3:45pm Competitive exclusion and coexistence in a two-strain pathogen model with diffusion

Prof. **Keng Deng**, University of Louisiana at Lafayette, USA

Chair: Prof. Cheng-Hsiung Hsu

3:45pm-4:15pm Tea break

4:15pm-4:45pm Synchronization of coupled cells

Prof. **Jui-Pin Tseng**, National Chengchi University

Chair: Prof. Chang-Hong Wu

4:50pm-5:20pm TBA

Dr. **Li-Chang Hung**, National Taiwan University

Chair: Prof. Chang-Hong Wu

May 22, 2016

9:00am-10:45am The entry-exit function and geometric singular perturbation theory

Prof. **Stephen Schecter**, North Carolina State University

Chair: Prof. Xiaoqiang Zhao

11:00am-11:30am R0 Analysis of a benthic-drift model for a stream population

Prof. **Yu Jin**, University of Nebraska-Lincoln, USA

Chair: Prof. Jian Fang

11:35am-12:05pm Global dynamics and traveling wave solutions of three species intraguild predator models

Prof. **Ting-Hui Yang**, Tamkang University

Chair: Prof. Jian Fang

12:05pm-2:00pm Lunch break

2:00pm-2:45pm Temporal patterns and circulation of influenza virus strains in Taiwan, 2008-2014: Implications of 2009 pH1N1 pandemic

Prof. **Ying-Hen Hsieh**, China Medical University

Chair: Prof. Jong-Sheng Guo

3:00pm-3:45pm Modified PNP_steric equations: a new model of ion transport through channels

Prof. **Tai-Chia Lin**, National Taiwan University

Chair: Prof. Chao-Nien Chen

3:45pm-4:15pm Tea break

4:15pm-4:45pm A general ODE model for population growth with many stages

Prof. **Yijun Lou**, The Hong Kong Polytechnic University, Hong Kong

Chair: Prof. Jui-Pin Tseng

4:50pm-5:20pm Stability of boundary layer solutions of Poisson-Nernst-Planck systems

Dr. **Chia-Yu Hsieh**, National Taiwan University

Chair: Prof. Jui-Pin Tseng

May 23, 2016

9:00am-9:45am On neural field models
Prof. **Chih-Wen Shih**, National Chiao Tung University

Chair: Prof. Keng Deng

9:45am-10:15am **Tea break**

10:15am-11:00am Epidemic models in multiplex networks
Prof. **Jongq Juang**, National Chiao Tung University

Chair: Prof. Keng Deng

11:15am-12:00pm Propagation phenomena for a reaction-advection-diffusion
competition model in a periodic habitat
Prof. **Xiaoqiang Zhao**, Memorial University of Newfoundland,
Canada

Chair: Prof. Sze-Bi Hsu

Abstract

Fronts and pulses in FitzHugh-Nagumo equations

Chao-Nien Chen

Department of Mathematics,

National Tsing Hua University

chen@math.nthu.edu.tw

There are many patterns and waves observed in FitzHugh-Nagumo equations. Fronts and pulses are basic local structures to be discussed in this talk.

Competitive Exclusion and Coexistence in a Two-Strain Pathogen Model with Diffusion

Keng Deng

Department of Mathematics, University of Louisiana at Lafayette

deng@louisiana.edu

We consider a two-strain pathogen model described by a system of reaction-diffusion equations. We define a basic reproduction number R_0 and show that when the model parameters are constant (spatially homogeneous), if $R_0 > 1$ then one strain will outcompete the other strain and drive it to extinction, but if $R_0 \leq 1$ then the disease-free equilibrium is globally attractive. When we assume that the diffusion rates are equal while the transmission and recovery rates are heterogeneous, then there are two possible outcomes under the condition $R_0 > 1$: 1) Competitive exclusion where one strain dies out. 2) Coexistence between the two strains. Thus, spatial heterogeneity promotes coexistence.

Bistable traveling waves for monotone semiflows

Jian Fang

Harbin Institute of Technology

jfang@hit.edu.cn

In this talk, I will first recall some classical results on the existence of traveling waves connecting two stable steady states for typical reaction-diffusion equations and their analogues. Such an existence result is then established for a class of bistable evolution systems in homogeneous/periodic environment from a monotone dynamical system point of view. Finally, the obtained results are illustrated with concrete models that may arise from population ecology. This talk is based on a joint work with Xiaoqiang Zhao.

**Traveling waves for a lattice dynamical system arising in
a diffusive endemic model**

Jong-Sheng Guo

Department of Mathematics, Tamkang University

jsguo@mail.tku.edu.tw

We are concerned with a lattice dynamical system modeling the evolution of susceptible and infective individuals at discrete niches. We prove the existence of traveling waves connecting the disease-free state to non-trivial leftover concentrations. We also characterize the minimal speed of traveling waves and prove the non-existence of waves with smaller speeds

**Temporal Patterns and Circulation of Influenza Virus Strains in Taiwan,
2008-2014: Implications of 2009 pH1N1 Pandemic**

Ying-Hen Hsieh^{1,2*}, Hsiang-Min Huang¹, Yu-Ching Lan³

¹Department of Public Health, ²Center for Infectious Disease Education and Research,

³Department of Health Risk Management, China Medical University, Taichung
Taiwan 40402

hsieh@mail.cmu.edu.tw

It has been observed that historically, strains of pandemic influenza led to succeeding seasonal waves, albeit with decidedly different patterns. Recent studies suggest that the 2009 A(H1N1)pdm09 pandemic has had an impact on the circulation patterns of seasonal influenza strains in the post-pandemic years. In this work we aim to investigate this issue and also to compare the relative transmissibility of these waves of differing strains using Taiwan influenza surveillance data before, during and after the pandemic.

We make use of the Taiwan Center for Disease Control and Prevention influenza surveillance data on laboratory-confirmed subtyping of samples and the Richards model to determine the waves of circulating (and co-circulating) H1, H3 and B virus strains in Taiwan during 2008-2014; or namely, short before, during and after the 2009 pandemic. We further pinpoint the turning points and relative transmissibility of each wave, in order to ascertain whether any temporal pattern exists.

For two consecutive years following the 2009 pandemic, A(H1N1)pdm09 circulated in Taiwan (as in most of Northern Hemisphere), sometimes co-circulating with AH3. From the evolution point of view, A(H1N1)pdm09 and AH3 were able to sustain their circulation patterns to the end of 2010. In fact, A(H1N1)pdm09 virus circulated in six separate waves in Taiwan between summer of 2009 and spring of 2014. Since 2009, a wave of A(H1N1)pdm09 occurred every fall/winter influenza season during our study period except 2011-2012 season, when mainly influenza strain B circulated.

Estimates of R for seasonal influenza are consistent with that of temperate and tropical-subtropical regions, while estimate of R for A(H1N1)pdm09 is comparatively less than countries in Europe and North America, but similar to that of tropical-subtropical regions. This offers indication of regional differences in transmissibility of influenza virus that exists only for pandemic influenza. Despite obvious limitations in the data used, this study, designed to qualitatively compare the temporal patterns and transmissibility of the waves of different strains, illustrates how influenza subtyping data can be utilized to explore the mechanism for various influenza strains to compete or to circulate, to possibly provide predictors of future trends in the evolution of influenza viruses of various subtypes, and perhaps more importantly, to be of use to future annual seasonal influenza vaccine design.

Stability of Boundary Layer Solutions of Poisson-Nernst-Planck Systems

Chia-Yu Hsieh

Department of Mathematics,

National Taiwan University

b92201049@gmail.com

The Poisson-Nernst-Planck (PNP) system has been widely used to describe the ion transport of ionic solutions, and plays a crucial role in the study of many physical and biological problems. In order to see Debye layers, which occur in ionic liquids near electrodes and have many applications in the fields of chemical physics and biophysics, boundary layer solutions need to be investigated. If the Robin boundary condition is imposed for the electrostatic potential, the PNP system admits a boundary layer solution as a steady state. We study the stability of boundary layer solutions of PNP system. By transforming the perturbed problem into another parabolic system with a new and useful energy law, we prove that the H^{-1} -norm of the solution of the perturbed problem decays exponentially.

The logo for NCTS (National Center for Teaching and Courseware) features the letters 'NCTS' in a bold, orange, sans-serif font. The letter 'C' is stylized with a white globe icon inside its central opening. The globe shows latitude and longitude lines.

R0 Analysis of a Benthic-Drift Model for a Stream Population

Yu Jin

Department of Mathematics,
University of Nebraska-Lincoln, USA
yjin6@unl.edu

One key issue for theory in stream ecology is how much stream flow can be changed while still maintaining an intact stream ecology, instream flow needs (IFNs); the study of determining IFNs is challenging due to the complex and dynamic nature of the interaction between the stream environment and the biological community. We develop a process-oriented benthic-drift model that links changes in the flow regime and habitat availability with population dynamics. In the model, the stream is divided into two zones, drift zone and benthic zone, and the population is divided into two interacting compartments, individuals residing in the benthic zone and individuals dispersing in the drift zone. We study the population persistence criteria, based on the net reproductive rate R_0 and on related measures. We develop new theory to calculate these quantities and use them to investigate how the various flow regimes, population birth rate, individual transfer rates between zones, and river heterogeneity affect population persistence. The theory developed here provides the basis for effective decision-making tools for water managers.

Epidemic Models in Multiplex Networks

Jonq Juang

Department of Applied Math, National Chiao Tung University,

Hsinchu, Taiwan

jjuang@math.nctu.edu.tw

In this talk, we consider epidemic models in multiplex networks in which the dynamics of susceptible-aware-susceptible(SIS) process in the physical world interplays with that of a cyclic process of unaware-aware-unaware(UAU) in the virtual world. Those models contain rich phase diagram of intertwined competition effects between three possible equilibria: the disease and information free equilibrium, the disease free and information saturated equilibrium, and epidemic and information saturated equilibrium. We will also present the global analysis of the models.

Modified PNP_steric equations: a new model of ion transport through channels

Tai-Chia Lin

Department of Mathematics, National Taiwan University

tclin@math.ntu.edu.tw

To describe ion transport through biological channels, we derive a new Poisson-Nernst-Planck (PNP) type model called the modified PNP_steric equations with derivative terms up to the fourth order using infinite expansion (in increasing order of derivatives) of the energy with the approximate Lennard-Jones (LJ) potential. The fourth-order derivative terms of the modified PNP_steric equations may stabilize the dynamics of the modified PNP_steric equations even though the coefficients of the second-order derivative terms are located in the symmetry breaking regime which may give multiple equilibriums of the original PNP_steric equations (with B. Eisenberg, *Nonlinearity* 28 (2015) 2053–2080). Our numerical results show that the energy of the modified PNP_steric equations may behave like a decreasing piecewise constant function of time. Such a model and computational method would be useful for the study of ion transport through channels. This is a joint work with Yi-Ping Lo and Chun-Hao Teng.

A general ODE model for population growth with many stages

Yijun Lou

Department of Applied Mathematics,
The Hong Kong Polytechnic University,
Hong Kong
yijun.lou@polyu.edu.hk

In this talk, I will present a model of ordinary differential equations for populations which are structured by many stages. The model is general enough to apply to many biological system. Our analysis identifies a basic reproduction number that acts as a threshold between population extinction and persistence. We establish conditions for the existence and uniqueness of nonzero equilibria and show that their local stability cannot be expected in general. Boundedness of solutions remains an open problem though we give some sufficient conditions.

This talk is based on joint work with Guiding Fan, Horst R. Thieme and Jianhong Wu.

**Spatial Heterogeneity and Time Periodicity in Lotka-Volterra
Competition-Diffusion Systems**

Wei-Ming Ni

Center for PDE, East China Normal University and School of Mathematics,
University of Minnesota
weiming.ni@gmail.com

In this lecture I shall report some of the recent progress on the 2x2 Lotka-Volterra competition-diffusion systems when spatial heterogeneity and/or temporal periodicity are present.

The entry-exit function and geometric singular perturbation theory

Stephen Schechter

Department of Mathematics, North Carolina State University, Raleigh,

NC, USA 27695-8205

schechter@ncsu.edu

Motivated by the problem of finding periodic traveling waves in the diffusive Holling-Tanner predator-prey model, we revisit the classical problem $\dot{x} = \varepsilon$, $\dot{z} = h(x, z)z$, with $h(x, 0) < 0$ for $x < 0$, $h(x, 0) > 0$ for $x > 0$, and $\varepsilon > 0$ small. This ODE admits solutions that start near the negative x -axis, rapidly approach it, drift along it, and eventually rapidly leave it. The relation between the limiting attraction and repulsion points is given by the well-known entry-exit function. For $h(x, z)z$ replaced by $h(x, z)z^2$, we explain this phenomenon using Geometric Singular Perturbation Theory (joint work with Peter De Maesschalck). It turns out that the linear case can be reduced to the quadratic case. We also discuss an even more recent approach to the entry-exit function, due to Ting-Hao Hsu, that uses the Exchange Lemma of GSPT and extra variables. Along the way we will give background about Geometric Singular Perturbation Theory, loss of normal hyperbolicity, and the Exchange Lemma.

On Neural Field Models

Chih-Wen Shih

Department of Applied Mathematics, National Chiao Tung University,

Hsinchu, Taiwan

cwshih@math.nctu.edu.tw

Neural fields model macroscopic parts of the cortex which involve several populations of neurons. In this lecture, I plan to introduce several neural field models which are represented by integro-differential equations with space-dependent transmission time delays. We then discuss absolute stability of the systems. This notion is associated with the neuronal dynamics in the sense that absolutely stable system evolves to a state which only depends on the input, not the initial state. We investigate absolute stability by a new approach termed sequential contracting, instead of the conventional Lyapunov functional technique. Sufficient conditions for the absolute stability, stability of the stationary solutions, and synchronization of the systems are then established, respectively.

This is a joint work with Chiu-Yen Kao and Chang-Hong Wu.

Synchronization of coupled cells

Jui-Pin Tseng

Department of Mathematical Sciences, National Chengchi University

jptseng@nccu.edu.tw

In this talk, we present a novel approach to establish synchronization of coupled cells and coupled systems. Under this approach, individual subsystems can be non-autonomous, and the coupling configuration is rather general. With an iteration scheme, the problem of synchronization is transformed into solving a corresponding linear system of algebraic equations. Subsequently, delay-dependent and delay-independent criteria for global synchronization can be established. We start by considering a cell-to-cell system under symmetric coupling to present the main idea of the approach. The framework is then extended to the N-cell system. The developed scheme can accommodate a wide range of coupled systems.

We demonstrate the applications of the present approach to establish synchronization for a gene regulation model and a neuronal model. This is a joint work with Chih-Wen Shih (NCTU).

An approach to the asymptotic behavior of traveling waves for some lattice dynamical systems

Chang-Hong Wu

Department of Applied Mathematics, National University of Tainan.

changhong@mail.nutn.edu.tw

We develop an approach to deal with the asymptotic behavior of traveling waves in a class of lattice dynamical system. Some applications will be discussed.

**Global dynamics and traveling wave solutions of three species
intraguild predator models**

Ting-Hui Yang

Department of Mathematics, Tamkang University

thyang@gms.tku.edu.tw

In this work, we consider the community of three species food web models with or without diffusion and the nonlinear interaction is the predator-prey Lotka-Volterra type. Without diffusion and in the absence of other species, each species follows the traditional logistical growth model and the top predator is an omnivore which is defined as feeding on the other two species. It can be seen as a model with one basal resource and two generalist predators, and pairwise interactions of all species are predator-prey type. It is well known that the omnivory module blends the attributes of several well-studied community modules, such as food chains (food chain models), exploitative competition (two predators-one prey models), and apparent competition (one predator-two preys models). With a mild biological restriction, we completely classify all parameters. All local dynamics and most parts of global dynamics are established corresponding to the classification. Moreover, the system is uniformly persistent whenever the coexistence appears. In the case of without diffusion, we conclude by discussing the strategy of inferior species to survive and the mechanism of uniform persistence for the three species ecosystem. With diffusion and presence of stable positive equilibrium, we show the existence of traveling wave front solution from the trivial solution to the positive equilibrium by the method of upper-lower solution. Some biological interpretation are also given.

**Propagation phenomena for a reaction-advection-diffusion competition
model in a periodic habitat**

Xiaoqiang Zhao

Memorial University of Newfoundland, Canada

zhao@mun.ca

In this talk, I will report our recent research on a reaction-advection-diffusion competition model in a periodic habitat. We first investigate the global attractivity of a semi-trivial steady state (i.e., the competitive exclusion) for the periodic initial value problem. Then we establish the existence of the rightward spreading speed and its coincidence with the minimal wave speed for spatially periodic rightward traveling waves. Further, we obtain a set of sufficient conditions for the rightward spreading speed to be linearly determinate. Finally, we apply the obtained results to a prototypical reaction-diffusion model. Our method involves monotone semiflows, principal eigenvalues, lower and upper solutions.

This talk is based on a joint work with Dr. Xiao Yu.
